

## The RSA Encryption Scheme

(p.1)

RSA is one of the first practical \_\_\_\_\_  
cryptosystems and is widely used in \_\_\_\_\_.  
In such a crypto system  
the encryption key is \_\_\_\_\_ and differs  
from the decryption key which is \_\_\_\_\_.  
In RSA, this asymmetry is based on the practical  
difficulty of \_\_\_\_\_.  
RSA is made of the initial letters of \_\_\_\_\_,  
\_\_\_\_\_, and \_\_\_\_\_.  
\_\_\_\_\_, who first publicly described the  
algorithm in \_\_\_\_\_.  
An \_\_\_\_\_ mathematician, had developed a  
quivalent system in \_\_\_\_\_, but it was not  
declassified until \_\_\_\_\_.  
In the RSA scheme any number of people can send  
each other messages, which \_\_\_\_\_ be read by \_\_\_\_\_.  
other than the \_\_\_\_\_. Each individual in the  
scheme finds two \_\_\_\_\_,  $p$  and  $q$ .  
Each person then calculates

$$n = \dots$$

Then an integer  $r$  is chosen that is \_\_\_\_\_  
\_\_\_\_\_. Finally,  $s$  is  
calculated so that

$\equiv$

The integers  $\dots$  and  $\dots$  are made  $\dots \dots$   
 (perhaps each person's  $\dots$  and  $\dots$  are published in  
 a directory)  $\dots$  while keeping  $\dots \dots \dots$ ,  
 and  $\dots$  secret.

Now suppose A wants to send a secret message to B  
 let us say the message

JON SKATES

First A must turn the message into a  $\dots \dots \dots$ .  
 It doesn't matter how so long as everyone does it the same  
 way, let us simply let  $A = \dots$ ,  $B = \dots$ ,  $C = \dots \dots \dots$ ,  
 $Z = \dots$ , space =  $\dots$ . The message is now the  
 number

$$M = \dots \dots \dots \dots \dots \dots \dots$$

Now  $\dots$  looks up  $\dots$ 's  $\dots$  and  $\dots$  in the  
 directory and calculates

$$E = \dots \dots \dots \dots \dots$$

and sends  $\dots$  to  $\dots$  as the encoded message.

$\dots$  decodes the message  $E$  by calculating  
 $\dots \dots \dots \dots \dots$

using his secret  $\dots$ . As we shall see

$$\dots \dots \dots = M$$

so that B recovers the message  $M$ .

The description here only works if  $M < \dots$ ;  
 if  $M > \dots$  then  $M$  must be  $\dots$   
 $\dots \dots \dots \dots \dots$ . The end  $\dots$   
 gets encoded as  $\dots \dots \dots$ , and decoded  
 by  $\dots \dots \dots$ .

Example:

Suppose A finds B's entry in the directory to be  
 $n = 11096351737$  and  $r = 684315297$ . This value of  $n$  is too small to use in practice (as we shall see), but it will do to illustrate the scheme. A breaks  $M$  into 10 digit pieces:

$$M_1 = \quad M_2 =$$

In general, if the last piece does not contain 10 digit sum — — — — — — — — — — — — Then using  
 $r = 684315297$  A calculates

$$E_1 \equiv$$

$$E_2 \equiv$$

Then A transmits  $E$  &  $B$  the message

$$E =$$

Now B breaks this up into 10 digit pieces

$$E_1 =$$

$$E_2 =$$

He knows his secret — which is — — — — — — — — — — — —  
 to calculate

$$M_1 \equiv$$

$$M_2 \equiv$$

(b. vi)

Thus B has recovered

$$M =$$

which easily translates to

Theorem (Proof of The Decoding Procedure)

Suppose  $p$  and  $q$  are distinct -----.

$$n = ,$$

Suppose the positive integer  $r$  satisfies -----  
and  $s$  is a positive integer such that -----

Let  $M$  be a positive integer. Suppose  $M < -----$   
and -----.

$$E \equiv$$

Then

$$\equiv M \pmod{ }.$$

PROOF: Suppose all the ~~for~~ hypotheses hold.

Since  $p$  and  $q$  are -----,

$$\phi(n) = .$$

Since  $r \not\equiv \pmod{ },$  there is  
a ----- integer  $d$  such that -----

We consider 2 cases.

We must show that -----

Case 1.  $(M, n) = 1$ . Then

Case 2  $(M, n) > 1$ . We may assume without loss of generality that  $\underline{\quad \quad \quad}$ .

## Security of the RSA Scheme

If a third party C can \_\_\_\_\_, that is if he can find \_\_\_\_\_ and \_\_\_\_\_, and then he can compute \_\_\_\_\_, and hence compute the secret key s using the \_\_\_\_\_ since

=

Thus the scheme is not secure unless

that C is \_\_\_\_\_.

A well chosen 2048 bit n is unlikely to be factored. This means that p and q should be about \_\_\_\_\_ bits; ie about \_\_\_\_\_ digits.

Is there a way to break the code without \_\_\_\_? Nobody has found one (or, if they have, they aren't telling).

## Advantages over traditional coding methods

In the usual coding schemes A and B have to agree on a secret key before they can start sending messages. If the communication of the secret key is \_\_\_\_\_, then \_\_\_\_\_.

In the RSA scheme, \_\_\_\_\_

Suppose k people wish to participate in an information network in such a way that no one can decode messages sent between any two others.

Then each pair needs a secret key; each person needs to keep track of \_\_\_\_\_ different secret keys.

(P.7)

Thus the total number of keys needed is \_\_\_\_\_.  
In the RSA scheme each person has only  
two keys, his \_\_\_\_\_ and \_\_\_\_\_;  
in all, only \_\_\_\_\_ keys.

### Finding large primes

How do we find a 300 digit prime?

One way is to \_\_\_\_\_ and  
\_\_\_\_\_. If it proves composite  
then \_\_\_\_\_. How many numbers can  
you expect to test before finding a prime?  
The Prime Number Theorem says that among the integers  
near  $x$  roughly one out of every \_\_\_\_\_  
is prime.

Since  $\log(10^{300}) = \dots \approx \dots$ ,  
you would expect to test about \_\_\_\_\_ numbers  
to find one that is prime.

### Some Algorithms

To implement the RSA algorithm we need

- (1) A method for computing \_\_\_\_\_.
- (2) An efficient method for computing \_\_\_\_\_.

(P.8)

## (1) Modular Inversion Algorithm

Input  $r$  and  $n$

Let  $s' = 0$  and  $s = 1$

while  $r > 0$  do

$$t \leftarrow n$$

$$n \leftarrow r$$

$$q \leftarrow [t/n]$$

$$r \leftarrow t - rq$$

$$u \leftarrow s$$

$$s \leftarrow s' - s q$$

$$s' \leftarrow u$$

Output  $s'$

STOP

When applying the Euclidean algorithm,  
we have at each stage we have

$$n = q_1 r + r_1$$

$$r_1 = 1 \cdot n - q_1 r$$

$$r = q_2 r_1 + r_2$$

:

$$r_1 = q_3 r_2 + r_3$$

:

:

:

$$r_j = (\cdot) n + s' r$$

$$r_{j+1} = (\cdot) n + s r$$

$$r_m = q_{m+1} r_{m+1} + r_{m+2}$$

$$r_{j+2} = r_j - q_{j+1} \cdot r_{j+1}$$

$$r_{m+1} = q_{m+1} r_{m+2} + 0$$

$$= (\cdot) n + s' r - q_{j+2} ((\cdot) n + s r)$$

where  $r_{m+2} = 1$

$$= (\cdot) n + (s' - q_{j+2} s) r$$

(P.9)

$$\text{Initially } (\cdot) = (\cdot)n + \dots r$$

$$r = (\cdot)n + \dots r$$

$$r_1 = (\cdot)n + \dots r$$

$$\text{So initially } s' = \dots \\ s = \dots$$

At first but when the algorithm finishes

=

and

### The Power Algorithm

We describe an efficient method for computing  $\dots$ .

First we describe an efficient method for computing powers.

82

As an example suppose we wish to compute  $a^{82}$  for some given  $a$ . The naive way would be to do  $\dots$  multiplications but this is clearly inefficient.

The idea is to convert 82 to binary

$82 =$

so that

$82 =$

We compute powers of  $a$  by doing repeated  $\dots$ :

$a^2,$

(P.10)

This takes    multiplications

Then we complete the computation of  $a^{82}$  by doing  
   more multiplications:

$$a^{82} =$$

This gives a total of    multiplications instead  
of   . This leads to the following algorithm:

#### The Power Algorithm

Input  $a$  and  $N$

Let  $j = 1$ ,  $Q = 1$ ,  $Y = 1$  and  $n = N$ .

while  $n > 0$  do

    if  $n$  is odd then

$b \leftarrow 1$

        if  $n = N$  then

$Q \leftarrow a$

$Y \leftarrow a$

        else

$Q \leftarrow Q^2$

$Y \leftarrow Q * Y$

    else

$b \leftarrow 0$

        if  $n = N$  then

$Q \leftarrow a$

        else

$Q \leftarrow Q^2$

$n \leftarrow [n/2]$

Output  $Y$

STOP

The input of this algorithm is       

The output is       .

(p. 11)

To compute  $a^N \pmod{m}$  requires a simple modification of the Power Algorithm. We need a function that does reduction mod m. One needs to define a function whose input is \_\_\_\_\_ and whose output is the \_\_\_\_\_:

$\text{mod}(a, m) =$  \_\_\_\_\_

#### The Power Algorithm mod m

Input  $a, N$  and  $m$

Let  $j = 1, Q = 1, Y = 1$  and  $n = N$ .

while  $n > 0$  do

if  $n$  is odd then

$b \leftarrow 1$

if  $n = N$  then

$Q \leftarrow a$

$Y \leftarrow a$

else

$Q \leftarrow \text{mod}(Q^2, m)$

$Y \leftarrow \text{mod}(Q * Y, m)$

else

$b \leftarrow 0$

if  $n = N$  then

$Q \leftarrow a$

else

$Q \leftarrow \text{mod}(Q^2, m)$

$n \leftarrow [n/2]$

Output  $Y$

STOP

The input of this algorithm is \_\_\_\_\_  
The output is \_\_\_\_\_.

True

# Observe that M1 == E1^s mod n and M2 == E2^s mod n
# and we are able to find M1, M2, M and the original message.

```

### Extra Credit Assignment

(a) Using the usual alphabet encoding encode the phrase

SEND MONEY

as three 8 digit numbers:

$$M_1 = 19051404, M_2 = , M_3 =$$

(b) Now use the RSA encryption scheme to

encode  $M_1, M_2, M_3$

with  $n = 536813567$ , and  $r = 3602561$

to obtain three numbers ( $< n$ ):

$$E_1 = 463099189, E_2 = , E_3 =$$

(c) Break the code by factoring  $n$  & obtaining the secret key  $s$ .

Explain clearly all your reasoning, work and detail of computations.

Check that  $E_1$  decodes as  $M_1$ , etc showing details.
