## Assignment 5 Solutions

4.3.10. A matrix $M \in M_{n \times n}(C)$ is called nilpotent if, for some positive integer $k, M^{k}=O$, where $O$ is the $n \times n$ zero matrix. Prove that if $M$ is nilpotent, then $\operatorname{det}(M)=0$.

Solution. If $O$ is the $n \times n$ zero matrix, then of course $\operatorname{det}(O)=0$. Recall that if $A, B \in M_{n \times n}(C)$, then $\operatorname{det}(A B)=\operatorname{det}(A) \operatorname{det}(B)$. It follows from an easy extension via induction that if $A_{1}, \ldots, A_{m} \in M_{n \times n}(C)$, then $\operatorname{det}\left(A_{1} \cdots A_{m}\right)=\operatorname{det}\left(A_{1}\right) \cdots \operatorname{det}\left(A_{m}\right)$.

Suppose now that $M \in M_{n \times n}(C)$ is nilpotent. Say $k \in \mathbb{N}$ is such that $M^{k}=O$. Then

$$
0=\operatorname{det}(O)=\operatorname{det}\left(M^{k}\right)=\operatorname{det}(M \cdots M)=\operatorname{det}(M) \cdots \operatorname{det}(M)=\operatorname{det}(M)^{k}
$$

so that $\operatorname{det}(M)=\sqrt[k]{0}=0$.
4.3.11. A matrix $M \in M_{n \times n}(C)$ is called skew-symmetric if $M^{t}=-M$. Prove that if $M$ if skew-symmetric and $n$ is odd, then $M$ is not invertible. What happens if $n$ is even?

Solution. Recall that if $A$ and $B$ are $n \times n$ matrices such that $B$ is obtained from $A$ by multiplying a row by a nonzero scalar $k \in C$, then $\operatorname{det}(B)=k \operatorname{det}(A)$. Now consider the matrix $k A$, which is obtained from multiplying every row of $A$, by $k$. It can be verified then that $\operatorname{det}(k A)=k^{n} \operatorname{det}(A)$. In particular, $\operatorname{det}(-A)=\operatorname{det}((-1) A)=(-1)^{n} \operatorname{det}(A)$.

Suppose now that $M \in M_{n \times n}(C)$ is skew-symmetric, and $n$ is odd. Then $\operatorname{det}(M)=\operatorname{det}\left(M^{t}\right)=\operatorname{det}(-M)=(-1)^{n} \operatorname{det}(M)$. As $n$ is odd, $(-1)^{n}=-1$ so that $\operatorname{det}(M)=-\operatorname{det}(M)$. The only number $x \in \mathbb{N}$ such that $-x=x$ is $x=0$. Hence, $\operatorname{det}(M)=0$ so $M$ is not invertible.

We cannot make many such conclusions about the invertibility if $n$ is even. Indeed, there exist even skew-symmetric matrices that are invertible, and those that are not invertible. The $2 \times 2$ zero matrix $O$ is clearly skew-symmetric, yet not invertible For any nonzero $a \in C, A=\left(\begin{array}{cc}0 & -a \\ a & 0\end{array}\right)$ is also skew-symmetric though will have nonzero determinant and hence be invertible.
4.3.14. Let $\beta=\left\{u_{1}, \ldots, u_{n}\right\}$ be a subset of $F^{n}$ containing $n$ distinct vectors, and let $B$ be the matrix in $M_{n \times n}(F)$ having $u_{j}$ as column $j$. Prove that $\beta$ is a basis for $F^{n}$ if and only if $\operatorname{det}(B) \neq 0$.

Solution. As $\beta$ consists of $n$ distinct vectors in an $n$-dimensional space, we have that $\beta$ is a basis for $F^{n}$ if and only if $\beta$ is linearly independent. As $B$ has $n$ linearly independent columns if and only if it has rank $n$, and these columns are precisely the vectors in $\beta$, we have that $\beta$ is linearly independent if and only if $B$ has rank $n$. However, $B$ has rank $n$ if and only if it is invertible, which it true if and only if $\operatorname{det}(B) \neq 0$.
